1 Introdução

Um somador vetorial é um componente essencial para realizar adições de números binários de forma simultânea. Este tipo de circuito é extremamente útil na computação, pois ele permite a soma rápida e eficiente de vetores de bits. A principal vantagem de um somador vetorial é a sua capacidade de operar de maneira paralela, o que significa que ele pode processar várias adições ao mesmo tempo, resultando em um aumento significativo na velocidade de processamento, quando comparado aos somadores sequenciais.

Todos os códigos utilizados nesse trabalho estão neste repositório do Github.

2 Projeto

O projeto do somador vetorial tem como objetivo desenvolver um código capaz de realizar operações de soma e subtração em vetores de diferentes tamanhos (4, 8, 16 e 32 bits). Utiliza-se a técnica de Carry-Lookahead para aumentar a eficiência das operações, pois ela permite calcular os *carries* antecipadamente, ao contrário do somador de Carry Ripple, que calcula junto a soma.

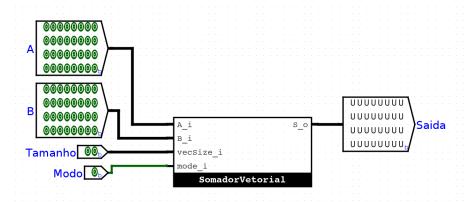

Figura 1: Módulo do somador vetorial

3 Funcionamento

O módulo possui quatro entradas:

- Dois vetores de 32 bits para os operandos, nomeados A_{-i} e B_{-i} .
- Um vetor de 2 bits que indica o tamanho dos números, chamado $vecSize_{-}i$: 4 bits = 00, 8 bits = 01, 16 bits = 10 e 32 bits = 11.
- Um bit que representa a operação a ser realizada, chamado mode_i : Soma = 0 e Subtração = 1.

A saída será um vetor de 32 bits, chamado S_{-0} , contendo o resultado da operação.

3.1 Blocos

Para que a operação seja realizada de forma correta, é necessário considerar a divisão dos vetores operandos em blocos com base no tamanho dos números, pois isso influencia a quantidade de operações e a propagação do carry. Especificamente, para vetores de 4 bits, serão realizadas 8 somas; para vetores de 8 bits, serão realizadas 4 somas; para vetores de 16 bits, serão realizadas 2 somas; e para vetores de 32 bits, será realizada 1 soma.

3.2 Operações

Para realizar a adição e subtração dos vetores, as entradas A e B foram combinadas bit a bit seguindo a lógica abaixo:

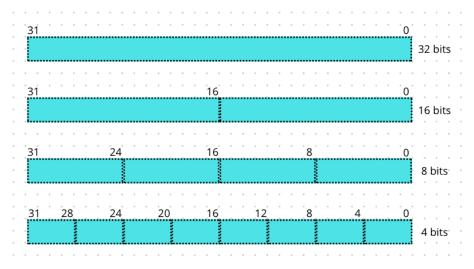

Figura 2: Divisão de blocos

A	В	Cin	Soma	Cout
0	0	0	0	0
0	1	0	1	0
1	0	0	1	0
1	1	0	0	1
0	0	1	1	0
0	1	1	0	1
1	0	1	0	1
1	1	1	1	1

Tabela 1: Somador 1 bit

$$Soma = A \cdot \bar{B} \cdot \bar{C}_{in} + \bar{A} \cdot B \cdot \bar{C}_{in} + \bar{A} \cdot \bar{B} \cdot C_{in} + A \cdot B \cdot C_{in}$$

$$= \bar{C}_{in} \cdot (A \cdot \bar{B} + \bar{A} \cdot B) + C_{in} \cdot (\bar{A} \cdot \bar{B} + A \cdot B)$$

$$= \bar{C}_{in} \cdot (A \oplus B) + C_{in} \cdot (A \odot B)$$

$$= (A \oplus B) \oplus C_{in}$$

$$C_{out} = A \cdot B \cdot \bar{C}_{in} + \bar{A} \cdot B \cdot C_{in} + A \cdot \bar{B} \cdot C_{in} + A \cdot B \cdot C_{in}$$
$$= A \cdot B(\bar{C}_{in} + C_{in}) + C_{in} \cdot (\bar{A} \cdot B + A \cdot \bar{B})$$
$$= A \cdot B + (A \oplus B) \cdot C_{in}$$

3.2.1 Adição

Na operação de adição, para cada bit i dos vetores de entrada A e B, e o vetor auxiliar de *carry_in*, é aplicada a seguinte expressão:

$$S(i) = A_i \oplus B_i \oplus C_i$$

Além disso, para a operação ser realizada de forma correta, o início de cada bloco do nosso vetor terá $carry_in$ 0.

3.2.2 Subtração

Na subtração, é necessário calcular o complemento a 2 do vetor B. Então, os bits do segundo vetor são invertidos, e o valor 1 é somado ao resultado. Para realizar essa soma na posição correta, foi definido que o carry_in do início de cada bloco tenha o valor 1. Por fim, a subtração é realizada de forma semelhante à adição, utilizando a expressão abaixo:

$$S_i = A_i \oplus (-B)_i \oplus C_i$$

3.2.3 Carry

O cálculo do *carry* é o ponto central para o funcionamento do projeto, pois a partir dele conseguiremos manipular se ele será propagado ou não em determinado segmento do vetor.

No início de cada bloco, o *carry* deve ter um valor pré-definido com base na operação que estamos realizando: 0 para soma e 1 para subtração. Os demais *carries* internos devem levar em consideração a propagação dos *carries* anteriores.

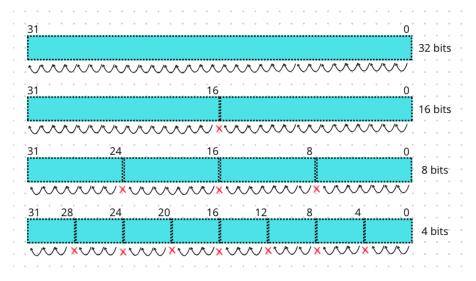

Figura 3: Propagação do carry

Para calcular os *carries* internos, utilizamos o método *Carry-Lookahead* (CLA), que calcula os *carries* de forma mais eficiente e paralela, em vez de sequencialmente. Esse método utiliza a ideia de gerar e propagar *carries* de modo que a expressão resultante dependa apenas do primeiro *carry* daquele bloco.

O CLA utiliza duas funções principais para calcular os carries de cada bit: Generate (G) e Propagate (P).

$$C_{i+1} = A_i \cdot B_i + (A_i \oplus B_i) \cdot C_i$$

- Gerar (G): Um bit gera um *carry* se tanto o bit do número A quanto o bit do número B são 1. Formalmente, $G_i = A_i \cdot B_i$.
- **Propagar (P)**: Um bit propaga um *carry* se pelo menos um dos bits do número A ou do número B é 1. Formalmente, $P_i = A_i + B_i$.

$$C_{i+1} = G_i + P_i \cdot C_i$$

Com essas funções, o carry para cada bit C_i pode ser calculado usando as seguintes fórmulas:

$$C_0 = carry_in$$

$$C_1 = G_0 + (P_0 \cdot C_0) =$$

$$C_2 = G_1 + (P_1 \cdot C_1) = G_1 + (P_1 \cdot (G_0 + (P_0 \cdot C_0)))$$

$$C_3 = G_2 + (P_2 \cdot C_2) = G_2 + (P_2 \cdot G_1 + (P_1 \cdot (G_0 + (P_0 \cdot C_0))))$$

$$\vdots$$

Para generalizar, o carry para o i-ésimo bit pode ser expresso como:

$$C_i = G_{i-1} + (P_{i-1} \cdot C_{i-1})$$

Portanto, criamos três vetores para esse processo:

- \bullet Os vetores c_-G e c_-P , que armazenam os valores de Carry Generate e Carry Propagate, respectivamente.
- O vetor c_-C , que armazena os valores de carry para cada índice do vetor.

Atribuímos a cada índice do vetor $c_{-}C$ a expressão equivalente para o tamanho atual dos números contidos no vetor, utilizando os valores de $c_{-}G$, $c_{-}P$ e o "carry_0" do bloco ao qual ele pertence.
